1. The 'Department' is already in the 3rd normalized form. It passes the 1st normalization because it has atomic valued ~~is~~ columns, all column have unique ~~value~~ names.

As it also has no partial dependency, like department_name, Manager_id, location_id all three dependence on primary key department_id, it passes 2nd normalization form.

On ~~contrary~~ contrary, the table has no transitive dependency as every column dependce only on ^{one} primary key. That's why it passes the third normalization form.
